

Outbound Voice Agent Assignment

Build an **outbound AI voice agent** using [LiveKit](#) for a healthcare use case.

The agent will call a person using provided information such as:

- Name
- Phone number
- Relevant health biomarkers (e.g., blood glucose, HbA1c)

During the call, the agent should inform the person about their health metrics and attempt to **schedule a doctor consultation**. You may use a **tool/function call** to simulate the appointment-booking process.

Post-Call Analysis

After the call ends, analyze the conversation and determine the outcome, including whether an appointment was successfully booked.

Opik Integration

Integrate [Opik](#) and send the relevant call information, including:

- Call metadata and variables
- Conversation/transcript
- Call recording or audio reference
- Tool calls/results
- Post-call analysis

Additionally, implement **at least one** [online evaluation](#) in **Opik** for the completed call. The evaluation criteria and approach are up to you. Opik integration should be implemented as a standalone, modular component (preferably a single file/module) that can be directly plugged into the LiveKit project with minimal changes to the core application.

Deliverables

- Working implementation
- README with setup and usage instructions
- Demonstration of the complete flow from outbound call to post-call analysis and Opik
- Opik trace/evaluation for the call
- Opik integration should be

The implementation will be reviewed in detail, and you should be prepared to **explain any part of the code, architecture, and technical decisions made in the solution**.
